ABSTRACT

A digital dubbing device (1) that compresses and
stores music data for each sound unit includes a music data
counter (22) that counts the number of samples of music
5   data when the music data is to be compressed, and detects a
music data stream located in the end part of the sound unit
from the music data based on TOC information of the music
data and the number of samples of the music data counted; a
data storage unit (60) that stores the music data stream
10   detected; a music data comparator (30) that detects a music
data stream identical to the music data stream stored from
the music data when dubbing of the music data is
interrupted; and a controller (80) that causes the dubbing
of the music data to be restarted from music data following
15   the music data stream detected.
